10.3 Controls on Cell Division

In the early 1980's, biologists were able to identify the substance in cells that regulates cell growth.

Cyclin: a protein which regulates the <u>timing</u> of the cell cycle in <u>eukaryotic</u> cells.

<u>Internal regulators</u>- <u>proteins that</u>
respond to events happening <u>inside</u> the
cells

External regulators- proteins that respond to events happening <u>outside</u> the cells

The <u>health</u> of an organism depends on cells <u>not</u> exceeding their <u>life</u> span.

This is especially <u>true</u> if it is a cell that divides <u>rapidly</u>.

What happens when a cell loses the ability to control its growth?

<u>Cancer</u>: a <u>disorder</u> in which the body's <u>own</u> cells lose the ability to <u>control</u> <u>growth</u> creating <u>tumors</u>.

Life Spans of Various Human Cells		
Cell Type	Life Span	Cell Division
Lining of esophagus	2-3 days	Can divide
Lining of small intestine	1-2 days	Can divide
Lining of large intestine	6 days	Can divide
Red blood cells	Less than 120 days	Cannot divide
White blood cells	10 hours to decades	Many do not divide
Smooth muscle	Long-lived	Can divide
Cardiac (heart) muscle	Long-lived	Cannot divide
Skeletal muscle	Long-lived	Cannot divide
Neuron (nerve cell)	Long-lived	Most do not divide
